Just like FEM, MPM belongs to the family of Galerkin methods. There are **no elements** in MPM, so  $\text{MPM} \in \text{Element-free Galerkin (EFG)}$ .

- MPM particles correspond to FEM quadrature points, instead of elements. MPM typically uses one-point quadrature rule.
- MPM equations are derived using **weak formulation**.

TL; DR: use MLS shape function in MPM.

- Originally proposed in SIGGRAPH 2018<sup>1</sup>.
- Further improved in the SIGGRAPH Asia 2019 Taichi paper<sup>2</sup> to save memory bandwidth.
- Faster and easier to implement than classical B-spline MPM.
- Reason for simplicity and performance: MPM almost always uses the APIC transfer scheme, and MLS-MPM reuses APIC as much as possible.

In this lecture,

- Scalars are non-bold. E.g.,  $m_i$  and  $V_p^0$ .
- Vectors/matrices are bold lower-/upper-case letters respectively. E.g.,  $\mathbf{v}_p$  and  $\mathbf{C}_p$ .
- Subscript  $i$  for grid nodes;  $p$  for particles. E.g.,  $\mathbf{v}_i$  and  $\mathbf{v}_p$ .
- Superscripts are for time steps, e.g.  $\mathbf{x}_p^n$  and  $\mathbf{x}_p^{n+1}$ .

Constitutive  
models in MPM

Lagrangian  
forces in MPM

## ① Particle to grid (P2G)

- $\mathbf{F}_p^{n+1} = (\mathbf{I} + \Delta t \mathbf{C}_p^n) \mathbf{F}_p^n, \dots$  (**Deformation update**)
- $(m\mathbf{v})_i^{n+1} = \sum_p w_{ip} \{ m_p \mathbf{v}_p^n + [m_p \mathbf{C}_p^n - \frac{4\Delta t}{\Delta x^2} \sum_p V_p^0 \mathbf{P}(\mathbf{F}_p^{n+1})(\mathbf{F}_p^{n+1})^T](\mathbf{x}_i - \mathbf{x}_p^n) \}$  (**Grid momentum**)
- $m_i^{n+1} = \sum_p m_p w_{ip}$  (Grid mass)

## ② Grid operations

- $\hat{\mathbf{v}}_i^{n+1} = (m\mathbf{v})_i^{n+1} / m_i^{n+1}$  (Grid velocity)
- $\mathbf{v}_i^{n+1} = \text{BC}(\hat{\mathbf{v}}_i^{n+1})$  (Grid boundary condition. BC is the boundary condition operator.)

## ③ Grid to particle (G2P)

- $\mathbf{v}_p^{n+1} = \sum_i w_{ip} \mathbf{v}_i^{n+1}$  (Particle velocity)
- $\mathbf{C}_p^{n+1} = \frac{4}{\Delta x^2} \sum_i w_{ip} \mathbf{v}_i^{n+1} (\mathbf{x}_i - \mathbf{x}_p^n)^T$  (Particle velocity gradient)
- $\mathbf{x}_p^{n+1} = \mathbf{x}_p^n + \Delta t \mathbf{v}_p^{n+1}$  (Particle position)

Note that in classical B-spline MPM, deformation update usually happens after G2P.

# Deformation update

Material Point  
Methods: A  
Hands-on  
Tutorial

Yuanming Hu

Overview

Moving Least  
Squares MPM

Constitutive  
models in MPM

Lagrangian  
forces in MPM

Deformation gradients evolve because  $\nabla \mathbf{v} = \left. \frac{\partial \mathbf{v}^n}{\partial \mathbf{x}} \right|_{\mathbf{x}=\mathbf{x}_p^n} \neq \mathbf{0}$ .

(Local velocity field **is not constant**, so the material keeps deforming.)

Evaluating new deformation gradients:

$$\mathbf{F}_p^{n+1} = (\mathbf{I} + \Delta t \nabla \mathbf{v}) \mathbf{F}_p^n. \quad (1)$$

In MLS-MPM, APIC  $\mathbf{C}_p^n$  is used as an approximation of  $\nabla \mathbf{v}$ .  
Therefore in MLS-MPM we have

$$\mathbf{F}_p^{n+1} = (\mathbf{I} + \Delta t \mathbf{C}_p^n) \mathbf{F}_p^n. \quad (2)$$

# P2G: Computing internal forces

Material Point  
Methods: A  
Hands-on  
Tutorial  
Yuanming Hu

Overview

Moving Least  
Squares MPM

Constitutive  
models in MPM

Lagrangian  
forces in MPM

Recall that

$(m\mathbf{v})_i^n = \sum_p w_{ip} \{ m_p \mathbf{v}_p^n + [m_p \mathbf{C}_p^n - \frac{4\Delta t}{\Delta x^2} \sum_p V_p^0 \mathbf{P}(\mathbf{F}_p^{n+1})(\mathbf{F}_p^{n+1})^T](\mathbf{x}_i - \mathbf{x}_p^n) \}$  (Grid momentum).

Two momentum terms:

- APIC:  $w_{ip}[m_p \mathbf{v}_p^n + m_p \mathbf{C}_p^n(\mathbf{x}_i - \mathbf{x}_p^n)]$
- Particle elastic force (impulse):

$$\Delta t \mathbf{f}_{ip} = -w_{ip} \frac{4\Delta t}{\Delta x^2} \sum_p V_p^0 \mathbf{P}(\mathbf{F}_p^{n+1})(\mathbf{F}_p^{n+1})^T](\mathbf{x}_i - \mathbf{x}_p^n)$$

Assuming hyperelastic materials. Deriving  $\mathbf{f}_i$  using potential energy gradients:

$$U = \sum_p V_p^0 \psi_p(\mathbf{F}_p) \quad (3)$$

$$\mathbf{f}_i = -\frac{\partial U}{\partial \mathbf{x}_i} \quad (4)$$

$\psi_p$ : elastic energy density of particle  $p$ ;  $U$ : total elastic potential energy.

$V_p^0$ : particle initial volume.

# P2G: Computing nodal force $\mathbf{f}_i$

Yuanming Hu

Overview

Moving Least  
Squares MPM

Constitutive  
models in MPM

Lagrangian  
forces in MPM

BC in MPM should be applied on the grid. For all grid nodes  $i$  within the boundary:

$$\mathbf{v}_i^{n+1} = \text{BC}_{\text{sticky}}(\hat{\mathbf{v}}_i^{n+1}) = \mathbf{0} \quad (10)$$

$$\mathbf{v}_i^{n+1} = \text{BC}_{\text{slip}}(\hat{\mathbf{v}}_i^{n+1}) = \hat{\mathbf{v}}_i^{n+1} - \mathbf{n}(\mathbf{n}^T \hat{\mathbf{v}}_i^{n+1}) \quad (11)$$

$$\mathbf{v}_i^{n+1} = \text{BC}_{\text{separate}}(\hat{\mathbf{v}}_i^{n+1}) = \hat{\mathbf{v}}_i^{n+1} - \mathbf{n} \cdot \min(\mathbf{n}^T \hat{\mathbf{v}}_i^{n+1}, 0) \quad (12)$$

( $\mathbf{n}$ : surface normal)

Extras:

- 1 Adding gravity  $\hat{\mathbf{v}}_i^{n+1} + = \Delta t \mathbf{g}$
- 2 Moving collision object
- 3 Coulomb Friction

Lagrangian  
forces in MPM

Why is MLS-MPM (SIGGRAPH 2018) easier and faster than classical B-spline MPM (SIGGRAPH 2013)?

- 1 Directly reuse APIC  $C_p$  as an approximation of  $\nabla \mathbf{v}$  for deformation gradient update. No need to evaluate  $\nabla w_{ip}$  (Fewer FLOPs)
- 2 Easy to move deformation update from G2P to P2G, because we only need  $C_p$  for deformation update. (Fewer bytes to fetch from main memory)
- 3 In P2G, APIC and MLS-MPM momentum contribution can be fused, since they are both “MLS”. (Fewer FLOPs)

MLS-MPM is consistent with the weak formulation of the Cauchy momentum equation. See the original MLS-MPM paper<sup>4</sup> for a correctness proof.

Lagrangian  
forces in MPM

Common constitutive models in MPM:

- 1 Elastic objects: NeoHookean & Corotated
- 2 Fluid: Equation-of-States (EOS)
- 3 Elastoplastic objects (snow, sand etc.): Yield criteria: ad-hoc boxing<sup>5</sup>, Cam-clay<sup>6</sup>, Drucker-prager<sup>7</sup>, NACC, ...

Two critical aspects of a constitutive model in MPM:

- 1 (Elastic/plastic) deformation update
- 2 (PK1) stress evaluation

Yuanming Hu

Overview

Moving Least  
Squares MPM

Constitutive  
models in MPM

Lagrangian  
forces in MPM

Deformation update: simply  $\mathbf{F}_p^{n+1} = (\mathbf{I} + \Delta t \mathbf{C}_p^n) \mathbf{F}_p^n$ .

PK1 stresses of hyperelastic material models:

- Neo-Hookean:
  - $\psi(\mathbf{F}) = \frac{\mu}{2} \sum_i [(\mathbf{F}^T \mathbf{F})_{ii} - 1] - \mu \log(J) + \frac{\lambda}{2} \log^2(J)$ .
  - $\mathbf{P}(\mathbf{F}) = \frac{\partial \psi}{\partial \mathbf{F}} = \mu(\mathbf{F} - \mathbf{F}^{-T}) + \lambda \log(J) \mathbf{F}^{-T}$
- (Fixed) Corotated:
  - $\psi(\mathbf{F}) = \mu \sum_i (\sigma_i - 1)^2 + \frac{\lambda}{2} (J - 1)^2$ .  $\sigma_i$  are singular values of  $\mathbf{F}$ .
  - $\mathbf{P}(\mathbf{F}) = \frac{\partial \psi}{\partial \mathbf{F}} = 2\mu(\mathbf{F} - \mathbf{R}) + \lambda(J - 1)J\mathbf{F}^{-T}$

Cauchy stress  $\boldsymbol{\sigma} = \frac{1}{J} \mathbf{P} \mathbf{F}^T$  is usually unused in MPM.

More details: check out the SIGGRAPH 2016 MPM course<sup>8</sup>.

Yuanming Hu

Overview

Moving Least  
Squares MPM

Constitutive  
models in MPM

Lagrangian  
forces in MPM

Volume ratio  $J_p = V_p^n / V_p^0 = \det(\mathbf{F}_p^n)$ .

The simplest equation of state:  $p = K(1 - J)$ , Cauchy stress  $\boldsymbol{\sigma} = -p\mathbf{I}$ .  $K$ : bulk modulus.

Computing  $\det(\mathbf{F}_p^n)$  can be numerically unstable.

Recall that for  $\mathbf{F}_{2 \times 2}$ ,  $\det(\mathbf{F}) = \mathbf{F}_{00}\mathbf{F}_{11} - \mathbf{F}_{01}\mathbf{F}_{10}$ . The “-” operation leads to **catastrophic cancellation**. Same for  $\mathbf{F}_{3 \times 3}$  (Question: why doesn't this happen to NeoHookean/corotated materials?)

Deformation update: instead of maintaining  $\mathbf{F}_p$ , directly maintain  $J_p^n = \det(\mathbf{F}_p^n)$ :

$$\mathbf{F}_p^{n+1} = (\mathbf{I} + \Delta t \mathbf{C}_p^n) \mathbf{F}_p^n \quad (13)$$

$$\Rightarrow \det(\mathbf{F}_p^{n+1}) = \det(\mathbf{I} + \Delta t \mathbf{C}_p^n) \det(\mathbf{F}_p^n) \quad (14)$$

$$\Rightarrow J_p^{n+1} = (1 + \Delta t \text{tr}(\mathbf{C}_p^n)) J_p^n \quad (15)$$

Lagrangian  
forces in MPM

## Theorem

*(Existence of singular value decompositions) Every real matrix  $\mathbf{M}_{n \times m}$  can be decomposed into  $\mathbf{M}_{n \times m} = \mathbf{U}_{n \times n} \mathbf{\Sigma}_{n \times m} \mathbf{V}_{m \times m}^T$ , where  $\mathbf{U}$  and  $\mathbf{V}$  are orthonormal matrices, and  $\mathbf{\Sigma}$  is a diagonal matrix.*

Diagonal entries  $\sigma_i = \Sigma_{ii}$  are called **singular values**.

Lagrangian  
forces in MPM

Note that SVD is not unique. We additionally require

- $\det(\mathbf{U}) = \det(\mathbf{V}) = 1$ .
- $|\Sigma_{ii}|$  are sorted in decreasing order.
- Only the singular value with smallest magnitude can be negative.

## Example

```
U, sig, V = ti.svd(M) # sig is an NxN diagonal matrix.
```

models in MPM

Lagrangian  
forces in MPM

In hyperelastic settings:

$$\mathbf{F}_p = \mathbf{F}_{p,\text{elastic}} \mathbf{F}_{p,\text{plastic}}, \psi_p^n = \psi(\mathbf{F}_{p,\text{elastic}}),$$

i.e., the potential energy penalizes elastic deformation only.

## Example

“Box” yield criterion<sup>11</sup>: deformation update:

- 1 Evolve  $\hat{\mathbf{F}}_p^{n+1} = (\mathbf{I} + \Delta t \mathbf{C}_p^n) \mathbf{F}_{p,\text{elastic}}^n$
- 2 SVD:  $\hat{\mathbf{F}}_p^{n+1} = \mathbf{U} \hat{\Sigma} \mathbf{V}^T$
- 3 Clamping:  $\Sigma_{ii} = \max(\min(\hat{\Sigma}_{ii}, 1 + \theta_s), 1 - \theta_c)$  (forget about too large deformations)
- 4 Reconstruct:  $\mathbf{F}_{p,\text{elastic}}^{n+1} = \mathbf{U} \Sigma \mathbf{V}^T$ ; move clamped parts to  $\mathbf{F}_{p,\text{plastic}}^{n+1}$

TL; DR: Treat MPM particles as FEM vertices, and use FEM potential energy model. A triangular mesh is needed.

Benefits:

- (Compared to FEM): Self-collision is handled on the grid;
- (Compared to MPM): Numerical fracture is avoided due to the mesh connectivity.
- Can easily couple MPM and FEM.

Easy to implement in Taichi using AutoDiff: `ti example mpm_lagrangian_forces`

Upgrading Taichi: `pip install --upgrade taichi==0.6.22`

Use “**field**” instead of “**tensor**” since Taichi v0.6.22

- The name “**tensor**” is deprecated. Always use “**field**” instead.
- `ti.var` is deprecated. Use `ti.field` instead.
- Argument `dt` is deprecated. Use `dtype` instead.

## Declaring fields in Taichi

```
# particle_x = ti.Vector(3, dt=ti.f32, shape=1024)
particle_x = ti.Vector.field(3, dtype=ti.f32, shape=1024)
particle_F = ti.Matrix.field(3, 3, dtype=ti.f32, shape=1024)
# density = ti.var(dtype=ti.f32, shape=(256, 256))
density = ti.field(dtype=ti.f32, shape=(256, 256))
num_springs = ti.field(dtype=ti.i32, shape=())
```

# Fields := global variables in Taichi

Hands-on  
Tutorial  
Yuanming Hu

Overview

Moving Least  
Squares MPM

Constitutive  
models in MPM

Lagrangian  
forces in MPM

## Distinguishing global fields from local variables

Global variables are always declared with “field”. Local variables are always declared without “field”:

```
x = ti.Vector.field(3, dtype=ti.f32, shape=(128, 512)) # global

@ti.kernel
def foo():
    a = ti.Vector([0.2, 0.4]) # local
```

The word “field” refers to ...

- ① a component of a (database) record. For example, `mass` and `volume` properties of a particle array.
- ② a (physical) quantity that is assigned to every point in space. E.g., “velocity fields”, and “magnetic fields”. High-dimensional arrays of scalars/vectors/matrices are exactly “fields” sampled at discrete grid points.
